

The drone arm mounts to the body on the right 12.00 mm hole. The left 8 mm center hole and four 3.00 mm holes are meant to have the drone fan attached to it.

The overall structure represents a solid beam. I had created this design at first. Many of the drones I've seen in the real world and market have this similar beam design, and since the payload requirement wasn't too grand, I believe this simple design would have been adequate. I would've also liked to create a thicker arm design with a truss-like structure, but we already had one created. I predict that with longer drone arms, the load would be more distributed throughout the drone body rather than the drone body, and I had this designed in mind of Carbon Fiber, the structural rigidity should be good. The thrust-to-weight analysis and FEA I'm not able to predict and shall see during testing.
